Computer Science 302 Fall 2009 (Practice) Third Examination, November 12, 2009

## Name:\_\_

## The entire examination is 250 points.

- 1. True or False. [5 points each]
  - (a) \_\_\_\_\_ Using path compression and making sure to merge the small tree with the large tree, n operations for union/find may be done in O(n) time, given that you start with n singleton trees.
  - (b) \_\_\_\_\_ If a planar graph G (a graph is called *planar* if it can be embedded in a plane with no edge crossings) has n vertices, then G has O(n) edges.
  - (c) \_\_\_\_\_ Kruskal's algorithm is a greedy algorithm.
  - (d) \_\_\_\_\_ Greedy algorithms are used because they're quick and easy to write, but they're never optimal.
  - (e) \_\_\_\_\_ If a hash table has size 2n but holds only n items, and if the hash function is pseudo-random, then, with very high probability, there will be no collision.
- 2. Fill in the blanks (5 points each blank).
  - (a) A graph with 60 nodes has no more than \_\_\_\_\_ edges.
  - (b) An acyclic connected graph with n nodes has \_\_\_\_\_ edges.
  - (c) A strongly connected directed graph with *n* nodes must have at least \_\_\_\_\_\_ edges.
  - (d) If a hash function is used to build a search structure, not a perfect hash table, what properties should it have? (I want three properties.)

3. Give the best possible asymptotic time complexity of each of these code fragments.

```
(a) [10 points]
    int m = n*n;
    while (m > 0)
      {
        cout << "hello world" << endl;
        m = m/2;
     }
</pre>
```

(b) [10 points]

```
int m = n;
while (m > 0)
{
   for ( int i = 0; i < m ; i++ )
      cout << "hello world" << endl;
   m = m/2;
}</pre>
```

4. [20 points] Write an appropriate loop invariant for the **inner** loop in this function.

```
void bubblesort(vector<int> & x)
{
  for(int i = 0; i < x.size; i++)
   for(int j = x.size-1; j > i; j--)
    if(x[j] < x[j-1])
    {
      int temp = x[j];
      x[j] = x[j-1];
      x[j-1] = temp;
    }
}</pre>
```

- 5. [20 points] Write a complete C++ program that:
  - (a) prompts the user to enter three integers,
  - (b) reads three integers from the keyboard,
  - (c) writes the largest of those three numbers to the screen.

## 6. [30 points]

Consider the weighted directed graph represented by the matrix below. A blank entry indicates no edge.

- (a) Write the nodes in a topological order.
- (b) Solve the single source minimum weight path problem for this graph, with start node A. Your answer should consist of two arrays: minimum weights and back pointers.

	A	G	Η	Ι	L	M	0	R	Т
A		-1			7		1		
G						7		3	
H						8			
Ι			-3						
L				2				6	
M									
0			4						2
R									9
T						1			

7. [25 points] Explain how you would use a search structure to implement a sparse array. The space below should be sufficient, but you can write on the back of this page if necessary.

[30 points] In FORTRAN, all matrices (*i.e.*, arrays) are stored in column-major order, and indices always start at 1 (not 0, as with C++). A FORTRAN program contains a declaration for a 10 × 8 × 20 3-dimensional matrix of type FLOAT, called A. Each variable of type FLOAT uses two words (address locations).

The compiler allocates a block of space, starting with word 1025, for A. Where will the variable A(5,4,16) be stored? (FORTRAN uses parentheses instead of brackets to indicate array indices.)

9. [20 points] Explain when you could use the Floyd-Warshall algorith, and give pseudo-code.

10. [30 points] Walk through the steps of Dijkstra's algorithm to solve the single source minimum path problem for the graph shown below, where s is the start node.
