Computer Science 302 Fall 2012 (Practice) Third Examination, November 20, 2012

Name:_____

The entire examination is 250 points.

1. True or False. [5 points each]

   (a) _____ If a planar graph G (a graph is called *planar* if it can be embedded in a plane with no edge crossings) has n vertices, then G has $O(n)$ edges.

   (b) _____ Kruskal's algorithm is a greedy algorithm.

   (c) _____ Greedy algorithms are used because they're quick and easy to write, but they're never optimal.

   (d) _____ If a hash table has size $2n$ but holds only n items, and if the hash function is pseudo-random, then, with very high probability, there will be no collision.

2. Fill in the blanks (5 points each blank).

   (a) A graph with 60 nodes has no more than _____ edges.

   (b) An acyclic connected graph with n nodes has _____ edges.

   (c) A strongly connected directed graph with n nodes must have at least _____ edges.

3. Give the best possible asymptotic time complexity of each of these code fragments.

   (a) [10 points]

```
int m = n*n;
while (m > 0)
  {
   cout << "hello world" << endl;
   m = m/2;
  }
```

   (b) [10 points]

```
int m = n;
while (m > 0)
  {
   for ( int i = 0; i < m ; i++ )
     cout << "hello world" << endl;
   m = m/2;
  }
```

(c) [10 points]

```
int m = n;
while (m > 1)
  {
   m = sqrt(m);
   cout << "hello world" << endl;
  }
```

(Assume that the square root function truncates down to an integer; for example, the value of `sqrt(14)` is 3.)

4. [20 points] Write an appropriate loop invariant for the **inner** loop in this function.

```
void bubblesort(vector<int> & x)
 {
  for(int i = 0; i < x.size; i++)
   for(int j = x.size-1; j > i; j--)
    if(x[j] < x[j-1])
     {
      int temp = x[j];
      x[j] = x[j-1];
      x[j-1] = temp;
     }
}
```

5. [20 points] Find a minimum spanning tree for the weighted graph shown below.

6. [30 points]

Consider the weighted directed graph represented by the matrix below. A blank entry indicates no edge.

(a) Write the nodes in a topological order.

(b) Solve the single source minimum weight path problem for this graph, with start node A. Your answer should consist of two arrays: minimum weights and back pointers.

	A	G	H	I	L	M	O	R	T
A		-1			7		1		
G						7		3	
H						8			
I			-3						
L				2				6	
M									
O			4						2
R									9
T						1			

7. [25 points] Explain how you would use a search structure to implement a sparse array.

8. [30 points] In FORTRAN, all matrices (*i.e.*, arrays) are stored in column-major order, and indices always start at 1 (not 0, as with C++). A FORTRAN program contains a declaration for a $10 \times 8 \times 20$ 3-dimensional matrix of type FLOAT, called `A`. Each variable of type FLOAT uses two words (address locations).

The compiler allocates a block of space, starting with word 1025, for `A`. Where will the variable `A(5,4,16)` be stored? (FORTRAN uses parentheses instead of brackets to indicate array indices.)

9. [30 points] In pseudocode, or C++ code if you prefer, write code for the Bellman-Ford algorithm on a graph of n nodes, whose names are $1, 2, \ldots n$.

You are given a two dimensional array W, where $W(i, j)$ is the weight of the edge from Node i to Node j. If $W[i, j] = \infty$, there is no edge from i to j.

Do not write code for reading W; just assume that it's there as a global variable.

The output of your code will be a one-dimensional array V, where $V[i]$ is the minimum weight of any path from 1 to i, as well as a one-dimensional back pointer array B, where $B[i]$ is the next-to-the-last node of a least weight path from 1 to i.

$B[1]$ should be undefined for all i, and $B[i]$ should be undefined if $V[i] = \infty$, that is, if there is no path from 1 to i. Use the value ∞ for any undefined entry of B.

You may assume that there are no negative weight cycles.

Do not write declarations for V and B; just assume that they are declared outside your procedure. Also, do not write code to print out the values of those two arrays; simply assume that using the information you compute is someone else's job.

10. [30 points] In pseudocode, or C++ code if you prefer, write code for the Floyd-Warshall algorithm. on a graph of n nodes, whose names are $1, 2, \ldots n$.

    You are given a two dimensional array W, where $W[i, j]$ is the weight of the edge from Node i to Node j. If $W[i, j] = \infty$, there is no edge from i to j.

    Do not write code for reading W; just assume that it's there as a global variable.

    The output of your code will be a two-dimensional array V, where $V[i, j]$ is the minimum weight of any path from i to j, as well as a two-dimensional forward pointer array F, where $F[i, j]$ is the second node of a least weight path from i to j.

    $F[i, i]$ should be undefined for all i, and $F[i, j]$ should be undefined if $V[i, j] = \infty$. Use the value ∞ for any undefined entry of F.

    You may assume that there are no negative weight cycles.

    Do not write declarations for V and F; just assume that they are declared outside your procedure. Also, do not write code to print out the values of those two arrays; simply assume that using the information you compute is someone else's job.
